Lecture 10

## Spanners and Distance Estimation

## Distance Estimation Problem

Task: Given $v_{1}, v_{2} \in V$, what is the distance

$$
d_{G}\left(v_{1}, v_{2}\right)=\min \left\{\operatorname{len}(\pi): \pi \text { is a path from } v_{1} \text { to } v_{2}\right\}
$$

between $v_{1}$ and $v_{2}$ in $G$ ?

Can we compute $d_{G}\left(v_{1}, v_{2}\right)$ in a streaming fashion?

## Distance Estimation Problem

## Exact Distance Estimation in Data Streams:

Deciding whether two vertices are at distance exactly 3 (or at a larger distance) requires $\Omega\left(n^{2}\right)$ space, i.e., no sublinear space streaming algorithm exists.

## Approximate Distance Estimation:

Given $v_{1}, v_{2} \in V$, output estimated distance $\left.\widehat{d( } v_{1}, v_{2}\right)$ such that

$$
\left.d_{G}\left(v_{1}, v_{2}\right) \leq \widehat{d( } v_{1}, v_{2}\right) \leq t \cdot d_{G}\left(v_{1}, v_{2}\right)
$$

for some small value $t>1$.
What is the trade-off between space and approximation guarantee $t$ ?

## Algorithm

## Distance Estimation Algorithm:

Input: Vertices $v_{1}, v_{2}$, parameter $t$

1. $H \leftarrow \varnothing$
2. While(stream not yet empty)
a) Let $e=a_{1} a_{2}$ be next edge in stream
b) if $\left(d_{H}\left(a_{1}, a_{2}\right) \geq t+1\right)$ then

Example: $t=2$

$$
H \leftarrow H \cup\{e\}
$$

H: black edges
3. return $d_{H}\left(v_{1}, v_{2}\right)$
$d_{H}\left(a_{1}, a_{2}\right):=d_{(V, H)}\left(a_{1}, a_{2}\right)$ : Shortest path between $a_{1}$ and $a_{2}$ using only edges from $H$

## Analysis:

1. Approximation Guarantee?
2. Space?

## Algorithm: Approximation Guarantee

Theorem. $d_{G}\left(v_{1}, v_{2}\right) \leq d_{H}\left(v_{1}, v_{2}\right) \leq t \cdot d_{G}\left(v_{1}, v_{2}\right)$, for any pair of vertices $v_{1}, v_{2}$

## Proof.

- Let $\pi$ be a shortest $v_{1}, v_{2}$ path in $G$ and let $v_{1}=a_{0}, a_{1}, a_{2}, \ldots, a_{k}=v_{2}$ be the vertices in $\pi$ in order. Then, $d_{G}\left(v_{1}, v_{2}\right)=k$.

- Consider any index $i$ and let $e=a_{i-1} a_{i}$. Then:

If $e \in H$ then $d_{H}\left(a_{i-1}, a_{i}\right)=1$,
If $e \notin H$ then at time when $e$ appeared in the stream, we had $d_{H^{\prime}}\left(a_{i-1}, a_{i}\right) \leq t$, where $H^{\prime}$ was the value of $H$ at that time. Thus: $d_{H}\left(a_{i-1}, a_{i}\right) \leq t$.

- We therefore obtain:

$$
d_{H}\left(v_{1}, v_{2}\right) \leq \sum_{i=1}^{k} d_{H}\left(a_{i-1}, a_{i}\right) \leq k \cdot t=t \cdot d_{G}\left(v_{1}, v_{2}\right) .
$$

## Spanners

## Observe:

- Theorem on last slide holds for any pair of vertices $v_{1}, v_{2}$
- In particular, the construction of set $H$ is independent from $v_{1}, v_{2}$
- We can therefore estimate the distance of any pair of vertices using edges $H$ !

## Spanner:

- Set $H$ can be regarded as a data structure that allows us to query approximate distances
- Such a data structure is known as a $t$-Spanner, where $t$ indicates the approximation factor

## Algorithm: Space Complexity

## Space Complexity:

Clearly $\mathrm{O}(|H| \log n)$, but how large can $H$ get?
$\rightarrow$ Reduce to a question in extremal combinatorics!

Lemma. ( $V, H$ ) does not contain any cycle of length at most $t+1$.
Proof. (by contradiction)

- Suppose that ( $V, H$ ) contained a cycle $C$ of length at most $t+1$
- Let $e=u_{1} u_{2}$ be the last edge inserted into $H$ that completed the cycle $C$
- Then, since $C$ is of length at most $t+1, d_{H^{\prime}}\left(u_{1}, u_{2}\right) \leq t$, where $H^{\prime}$ was the value of $H$ when $e$ was inserted
- Contradiction to the fact that algorithm would then not have inserted $e$ into $H$.

## Algorithm: Space Complexity

Definition (girth): The girth $\gamma(G)$ of a graph $G$ is the length of its shortest cycle.
Observe: $(V, H)$ has girth $t+2$

## Extremal Combinatorics:

What is the maximum number of edges that a graph of girth $k$ can have?

Theorem. Let $G=(V, E)$ be an $n$-vertex graph with $m$ edges and girth $\gamma(G) \geq k$. Then:

$$
m \leq n+n^{\left.1+\frac{1}{2}\right\rfloor}
$$

Corollary. The space complexity of our algorithm is $O\left(n^{1+\frac{2}{t}} \log n\right)$.

$$
|H| \leq n+n^{1+\frac{1}{\left[\frac{t+2-1}{2}\right]}}=n+n^{1+\frac{1}{\left[\frac{t+1}{2}\right]}} \leq n+n^{1+\frac{1}{2}}=n+n^{1+\frac{2}{t}}=O\left(n^{\left.1+\frac{2}{t}\right)}\right.
$$

(using $\left\lfloor\frac{t+1}{2}\right\rfloor \geq \frac{t}{2}$ which holds for integral $t$ )

## Algorithm: Space Complexity

Lemma. Let $G$ be an $n$-vertex graph with average degree $d=\frac{2 m}{n}$. Let $F$ be the graph obtained from $G$ by repeatedly deleting nodes of degree at most $\frac{d}{2}$. Then:

- The minimum degree in $F$ is at least $\frac{d}{2}$.
- $F$ is non-empty.

## Proof.

By contradiction, suppose that $F$ is empty. Then, when we removed the last vertex $v$, we removed no incident edge to $v$. We therefore removed at most $\frac{(n-1) d}{2}=$ $m \frac{n-1}{n}$ edges and thus there are $\frac{m}{n}$ edges left in $F$, a contradiction to $F \stackrel{2}{\text { being }}$ empty.

## Algorithm: Space Complexity

Theorem. Let $G=(V, E)$ be an $n$-vertex graph with $m$ edges and girth $\gamma(G) \geq k$. Then:

$$
m \leq n+n^{1+\frac{1}{\left\lfloor\frac{k-1}{2}\right]}}
$$

## Proof:

- Let $d=\frac{2 m}{n}$ be the average degree.
- If $d \leq 4$ then $m \leq 2 n$ which implies the theorem. Suppose hence that $d>4$.
- Let $F$ be graph obtained by repeatedly removing from $G$ all vertices of degree at most $\frac{d}{2}$. Then, $F$ has minimum degree $\frac{d}{2}$ and is non-empty.
- Let $l=\left\lfloor\frac{k-1}{2}\right\rfloor$ and observe that $\gamma(F) \geq \gamma(G) \geq k$.

- Consider any vertex $v$. The distance-l neighborhood of $v$ is acyclic and therefore a tree (if not then there was a cycle of length less than $k$ ). The branching factor of this tree is at least $\frac{a}{2}-1>1$ (using $d>4$ ). The tree therefore has at least $\left(\frac{d}{2}-1\right)^{l}$ vertices. Hence,

$$
n \geq\left(\frac{d}{2}-1\right)^{l}=\left(\frac{m}{n}-1\right)^{l} \Rightarrow m \leq n+n^{1+\frac{1}{l}}
$$

## Summary

## Summary:

- There is a streaming algorithm with space $O\left(n^{1+\frac{2}{t}} \log n\right)$ for computing a tspanner.
- For $t \geq 3$, the space bound is $o\left(n^{2}\right)$ !
- Analysis: Space complexity inherent in algorithm, can be bounded by a result from extremal combinatorics
- Slightly improved bounds are possible (see references)
